EZ ChIP™
Chromatin Immunoprecipitation Kit
Catalog # 17-371
Instruction Manual

Sufficient reagents for 22 chromatin immunoprecipitation (ChIP) assays per kit.

FOR IN VITRO RESEARCH USE ONLY.
NOT RECOMMENDED OR INTENDED FOR DIAGNOSIS OF DISEASE IN HUMANS.
DO NOT USE IN HUMANS.
I. INTRODUCTION

Chromatin Immunoprecipitation (ChIP) is a widely used method to identify specific proteins associated with a region of the genome, or in reverse, to identify regions of the genome associated with specific proteins. These proteins can be isoforms of histones modified at a particular amino acid or other chromatin associated proteins. When employed with antibodies that recognize histone modifications, ChIP can be used to “measure” the amount of the modification. An example of this would include measurement of the amount of histone H3 acetylation associated with a specific gene promoter region under various conditions that might alter expression of the gene. Histones are not the only proteins that can be studied using this technique. Much of the recent interest has been in analyzing transcription factor distribution throughout the genome or at specific loci.

When performing ChIP, cells are first fixed with formaldehyde to crosslink proteins to DNA and then chromatin is harvested from the cells and subjected to an immunoselection process, which requires the use of specific antibodies. Any DNA sequences cross-linked to the protein of interest will co-precipitate as part of the chromatin complex. After the immunoselection of chromatin fragments and purification of associated DNA, the detection of specific DNA sequences is performed. If the DNA which will be detected is associated with the protein or histone modification being examined, the relative representation of that DNA sequence will be increased (or enriched) by the immunoprecipitation process.

Generally, standard PCR is performed to identify the DNA sequence (the gene or region of the genome) associated with the protein of interest. The relative abundance of a specific DNA sequence isolated via the protein-specific immunoselection is compared to DNA obtained when using an unrelated antibody control. DNA fragments are run on gels to facilitate quantitation of the PCR products. A much more accurate alternative to standard PCR is real time quantitative PCR (RT-qPCR). Cloning of sequences from a ChIP experiment is also possible, to create libraries of fragments that are enriched for those that interact with a particular protein. The combination of chromatin IP with microarray applications (ChIP on chip) is a novel technique that is becoming more popular, allowing the generation of genome-wide maps of protein-DNA interactions or histone modifications.

The EZ ChIP™ kit contains the buffers and reagents required to perform a successful ChIP from mammalian cells. Importantly, EZ ChIP™ also contains essential controls (anti-RNA Polymerase II, Normal Mouse IgG and Control Primers) to ensure that the user has successfully performed the ChIP assay. RNA Polymerase II is responsible for the transcription of protein coding genes, and therefore, is present at the promoter region of genes that are actively transcribed. The glyceraldehyde-3-phosphate dehydrogenase (GAPDH) gene is considered a housekeeping gene and expected to be undergoing transcription in most growing mammalian cells. Upon immunoprecipitation of chromatin with an antibody to RNA Polymerase II, the resulting DNA is enriched for the GAPDH gene (as well as all transcribed genes), whereas immunoprecipitation with Normal Mouse IgG will not result in GAPDH enrichment. The covalent bonds between the DNA and associated proteins are then severed, and DNA purified prior to performing PCR. For DNA purification, the EZ ChIP™ kit incorporates a unique polypropylene spin column manufactured by Mo Bio Laboratories, Inc. Each spin column contains a specially activated silica membrane filter that captures DNA and separates it from contaminating proteins and other cellular debris. After soluble contaminants are spun through the filter, the column is washed and then DNA is eluted in a low-salt buffer. Bind Buffer “A”, Wash Buffer “B”, and Elute Buffer “C” are supplied by Mo Bio Laboratories and are RNase and DNase free. This technology from Mo Bio Laboratories, Inc. provides rapid purification of chromatin DNA without the need for phenol chloroform extractions or ethanol precipitation. The purified DNA is subjected to PCR using the Control Primers which are specific to the promoter region of the GAPDH gene.
Kit Description

Quantity: Two boxes containing the necessary reagents to perform 22 chromatin immunoprecipitation (ChIP) assays. This kit also contains reagents to generate chromatin from ten 10-cm plates to allow for multiple immunoprecipitations from the same chromatin preparation.

Storage and Stability: Upon receipt, store components at the temperatures indicated on the labels. Storage temperatures are also indicated on page 4 of this manual. Kit components are stable for 1 year from date of shipment when stored as directed.

Use: The EZ ChIP™ kit contains reagents optimized for immunoprecipitation of chromatin from mammalian cells including controls to ensure successful performance of this assay. The included positive control antibody is a mouse monoclonal antibody to RNA Polymerase II and will detect RNA Polymerase II of human, mouse, rat and yeast. The negative control is Normal Mouse IgG, which controls for the non-specific immunoselection of chromatin by immunoglobulins. Control Primers and 10X PCR Buffer are included for detection of a 166 base pair region of the human GAPDH promoter by PCR. Use of these primers for DNA from other species is not recommended. Detection of the DNA region, gene or promoter of interest in immunoprecipitated chromatin must be empirically determined by the researcher. PCR using promoter-specific primers is recommended for detection and analysis of enriched DNA.

The EZ ChIP™ kit has all the necessary buffers and reagents to perform successful chromatin immunoprecipitation assays, however, careful attention must be paid to the details of the instructions. Follow all the instructions carefully, especially with regard to incubation times and temperatures.

II. CHROMATIN IP ASSAY OVERVIEW

A. Chromatin Sample Prep and Immunoselection

**Grow cells and formaldehyde treat.** This treatment crosslinks the proteins to the DNA ensuring co-precipitation of the DNA with the protein of interest.

**Lysis and sonication of the cells.** Cells are broken open and sonication is performed to shear the chromatin to a manageable size. Generally, 200-1000bp of DNA is small enough to achieve a high degree of resolution during the detection step. It is critical that average size be confirmed empirically by gel electrophoresis.

**Immunoselection.** Very similar to a standard immunoprecipitation by using a primary antibody of choice followed by Protein G-conjugated agarose beads as the secondary reagent. This enriches for the protein of interest and the DNA that it is specifically complexed with.

B. DNA Purification and Detection

**Purification of the DNA.** Protein-DNA crosslinks are reversed during incubation at 65°C and DNA is purified to remove the chromatin proteins and to prepare the DNA for the detection step.

**Detection.** This is the most variable step of the procedure because of the number of detection methods that can be employed and the variability of PCR primer selection. The most meaningful results will be obtained with quantitative PCR for this step. Real Time Quantitative PCR (RT-qPCR) is ideal, but this method requires a specialized PCR machine that may not be available. For standard PCR, primer selection is critical and must be designed with close adherence to the following guidelines:

- Primer Length: 24 nt
- Optimum Tm: 60°C
- Optimum GC: 50%
- Amplicon size: 100-700 base pairs

After standard PCR, the fragments are run on agarose or polyacrylamide gels, and the gels are stained and imaged as appropriate.
III. EZ ChIP™ KIT COMPONENTS

A. Provided Kit Components (Note Storage Temperatures)

**Store at 4°C:**

- **Protein G Agarose/Salmon Sperm DNA**, Catalog # 16-201. One vial containing 1.5ml packed beads with 600µg sonicated salmon sperm DNA, 1.5mg BSA and approximately 4.5mg recombinant Protein G. Provided as a 50% gel slurry for a final volume of 3ml per vial. Suspended in TE buffer, pH 8.0, containing 0.05% sodium azide. Liquid suspension.

- **ChIP Dilution Buffer**, Catalog # 20-153. One vial containing 24ml of 0.01% SDS, 1.1% Triton X-100, 1.2mM EDTA, 16.7mM Tris-HCl, pH 8.1, 167mM NaCl.

- **Low Salt Immune Complex Wash Buffer**, Catalog # 20-154. One vial containing 24ml of 0.1% SDS, 1% Triton X-100, 2mM EDTA, 20mM Tris-HCl, pH 8.1, 150mM NaCl.

- **High Salt Immune Complex Wash Buffer**, Catalog # 20-155. One vial containing 24ml of 0.1% SDS, 1% Triton X-100, 2mM EDTA, 20mM Tris-HCl, pH 8.1, 500mM NaCl.

**Store at -20°C:**

- **Protease Inhibitor Cocktail II**, Catalog # 20-283. Two vials, each containing 110µl of 200X Protease Inhibitor Cocktail II in DMSO.

- **RNase A**, Catalog # 20-297. One vial containing 600µg of RNase A in 60µl sterile water.

- **Proteinase K**, Catalog # 20-298. One vial containing 600µg of Proteinase K in 60µl of 50mM Tris-HCl, pH 8.0, 10mM CaCl2.

- **1M NaHCO3**, Catalog # 20-296. One vial containing 600µl of 1M NaHCO3.

- **10X PCR Buffer**, Catalog # 20-295. One vial containing 200µl of 750mM Tris-HCl, pH 8.8, 200mM (NH4)2SO4, 0.1% Tween®-20, 25mM MgCl2.

- **Control Primers**, Catalog # 22-004. One vial containing 75µl of 5µM of each control primer specific for human GAPDH.
  
  **FOR:** 5'-TACTAGCGGTTTTACGGGCG-3'
  
  **REV:** 5'-TCGAACAGGAGGAGCAGAGAGCGA-3'

- **Anti-RNA Polymerase II**, clone CTD4H8, Catalog # 05-623B. One vial containing 25µg of Anti-RNA Polymerase II, clone CTD448.

- **Normal Mouse IgG**, Catalog # 12-371B. One vial containing 25µg of normal mouse IgG.

**Store at Room Temperature:**

- **20% SDS**, Catalog # 20-280. One vial containing 242µl of 20% SDS.

- **Spin Filters**, Catalog # 20-290. One bag containing 22 Spin Filters in Collection Tubes.

- **Collection Tubes**, Catalog # 20-291. One bag containing 22 Collection Tubes.

- **Bind Reagent A**, Catalog # 20-292. One vial containing 25ml of Bind Reagent A.

- **Wash Reagent B**, Catalog # 20-293. One vial containing 12.5ml of Wash Reagent B.

- **Elution Reagent C**, Catalog # 20-294. One vial containing 1.5ml of Elution Reagent C.
B. **Required Materials Not Provided**

**Reagents**
- Cells, stimulated or treated as needed for the experimental system
- Antibody of interest for chromatin immunoprecipitation
- 37% Formaldehyde
- Taq DNA polymerase
- dNTPs, 2.5mM each
- DNase and RNase free sterile H₂O

**Equipment**
- Vortex mixer
- Rotating wheel/platform
- Timer
- Variable volume (5-1000µl) pipettes + tips
- Microfuge
- Variable temperature water bath
- Cell scraper
- Sonicator
- Microfuge tubes, 1.5ml
- Thermal cycler
- PCR tubes, 0.2ml
- Filter-tip pipette tips
IV. CHROMATIN IMMUNOPRECIPITATION PROTOCOL

A. In Vivo Crosslinking and Lysis

Prior to starting this section:

- Stimulate or treat, if necessary, adherent mammalian cells at ~80-90% confluency in a 100mm culture dish containing 10ml of growth media.
  - For HeLa cells, this is approximately 2 x 10^7 cells. This will generate a preparation of chromatin that can be used for up to 10 separate immunoprecipitations.
  - Include one extra dish to be used solely for estimation of cell number.
- Obtain ice for incubation of PBS (see Step 3) and for incubating culture dish (see Step 6).
- Prepare 21ml of 1X PBS (2.1ml 10X PBS and 18.9ml water) for each 100mm culture dish and put on ice. This will be used for washes and needs to be ice cold.
- Warm SDS Lysis Buffer to room temperature to ensure SDS is in solution before proceeding with cell lysis.
- Remove Protease Inhibitor Cocktail II and thaw at room temperature for use in Step 3 and 13. This product contains DMSO and will remain frozen below 18.4°C.

1. Add 270µl of 37% formaldehyde (or 540µl of fresh 18.5% formaldehyde) to 10ml of growth media to crosslink and gently swirl dish to mix.
   - Final concentration is 1%.
   - Use high quality formaldehyde. Do not use if formaldehyde is past the expiration date as suggested by the manufacturer. To make fresh formaldehyde before each experiment, see Appendix B.
2. Incubate at room temperature for 10 minutes.
   - Agitation of cells is not necessary.
3. Meanwhile, remove 1ml of ice cold 1X PBS to a separate tube for every dish and add 5µl of Protease Inhibitor Cocktail II to each 1ml of 1X PBS and put on ice.
4. Add 1ml of 10X Glycine to each dish to quench unreacted formaldehyde.
5. Swirl to mix and incubate at room temperature for 5 minutes.
6. Place dish on ice.
7. Aspirate medium, removing as much medium as possible, being careful not to disturb the cells.
8. Add 10ml of cold 1X PBS to wash cells.
10. Add 1ml cold PBS containing 1X Protease Inhibitor Cocktail II to dish (made in Step 3).
11. Scrape cells from each dish into a microfuge tube.
12. Spin at 700 x g at 4°C for 2-5 minutes to pellet cells.
13. During spin, add 5µl of Protease Inhibitor Cocktail II to each 1ml of SDS Lysis Buffer required.
   - For every 2 x 10^7 HeLa cells, 1ml of SDS Lysis Buffer is recommended for this protocol. Adjust accordingly if different cell concentrations are desired as the ratio of lysis buffer to cell density is important for reliable cell lysis.
14. Remove supernatant. (Cell pellet can be frozen at -80°C at this step.)
15. Resuspend cell pellet in 1ml of SDS Lysis Buffer containing 1X Protease Inhibitor Cocktail II.
16. Aliquot between 300-400µl per microfuge tube. (Lysate can be frozen at -80°C at this step.)
17. If optimal conditions for sonication have already been determined, proceed to Section B. Otherwise, see Appendix A.
B. Sonication to Shear DNA

Prior to starting this section:

Optimal conditions required for shearing crosslinked DNA to ~200-1000 base pairs in length need to be determined. See Appendix A for a protocol. Once optimal shearing conditions have been determined, proceed with the steps below.

1. If desired, remove 5\(\mu\)l of cell lysate from Section A, Step 17 for agarose gel analysis of unsheared DNA.
   - If cell lysate from Section A, Step 17 was previously frozen, thaw on ice.
2. Sonicate cell lysate on wet ice.
   - HeLa cells in SDS Lysis Buffer at a cell concentration of 2 x 10^7 per ml sheared with 4-5 sets of 10-second pulses on wet ice using a Cole Parmer, High Intensity Ultrasonic Processor/Sonicator, 50-watt model equipped with a 2mm tip and set to 30% of maximum power gave the appropriate length DNA fragments. See Figure A (page 12).
   - Keep cell lysate ice-cold. Sonication produces heat, which can denature the chromatin.
3. Spin at 12,000-15,000 x g at 4°C for 10 minutes to remove insoluble material.
4. If desired, remove one 5\(\mu\)l aliquot for agarose gel analysis of the sheared DNA.
   - To prepare an aliquot for agarose gel analysis, join the protocol in Appendix A at Step 7.
5. Remove supernatant to fresh microfuge tubes in 100\(\mu\)l aliquots.
   - Each 100\(\mu\)l aliquot contains 2 x 10^6 cell equivalents of lysate which is enough for one immunoprecipitation.
   - Sheared crosslinked chromatin can be stored at -80°C for up to a few months.

C. Immunoprecipitation (IP) of Crosslinked Protein/DNA

Prior to starting this section:

- Remove Protease Inhibitor Cocktail II and thaw at room temperature for use in Step 3. This product contains DMSO and will remain frozen below 18.4°C.

1. Prepare enough Dilution Buffer containing protease inhibitors for the number of desired immunoprecipitations and store on ice.
   - Each IP requires the addition of 900\(\mu\)l of Dilution Buffer and 4.5\(\mu\)l of Protease Inhibitor Cocktail II.
   - Samples include the positive control, Anti-RNA Polymerase II, and the negative control, Normal Mouse IgG, and the antibody of interest (user supplied). It is recommended that the user include a negative control IgG of the same species as the antibody of interest.
2. Prepare one microfuge tube containing 100\(\mu\)l of sheared crosslinked chromatin (Section B, step 5) for the number of desired immunoprecipitations and put on ice. If chromatin has been previously frozen, thaw on ice.
   - Alternatively, if multiple immunoprecipitations will be performed from the same chromatin preparation, place the entire volume for the number of desired immunoprecipitations in one large tube that will be able to accommodate a volume of 1.1ml for each IP.
   - Each 100\(\mu\)l will contain ~2 x 10^6 cell equivalents of chromatin.
3. Add 900\(\mu\)l of Dilution Buffer containing Protease Inhibitor Cocktail II into each tube containing 100\(\mu\)l of chromatin.
   - Alternatively, if multiple immunoprecipitations will be performed from the same chromatin preparation, use the appropriate volume of Dilution Buffer containing Protease Inhibitor Cocktail II for the correct number of immunoprecipitations.
4. Add 60µl of Protein G Agarose for each IP.
   - The Protein G Agarose is a 50% slurry. Gently mix by inversion before removing.
   - This step serves to “preclear” the chromatin, i.e., to remove proteins or DNA that may bind nonspecifically to the Protein G agarose.
   - Alternatively, if multiple immunoprecipitations will be performed from the same chromatin preparation, use the appropriate volume of Protein G Agarose for the correct number of immunoprecipitations.

5. Incubate for 1 hour at 4°C with rotation.

6. Pellet agarose by brief centrifugation (3000-5000 x g for 1 minute).
   - Do not spin Protein G Agarose beads at high speeds. Applying excessive g-force may crush or deform the beads and cause them to pellet inconsistently.

7. Remove 10µl (1%) of the supernatant as Input and save at 4°C until Section D, step 1.
   - If different chromatin preparations are being carried together through this protocol, remove 1% of the chromatin as Input from each.

8. Collect the supernatant by aliquoting 1ml into fresh microfuge tubes.

9. Add the immunoprecipitating antibody to the supernatant fraction:
   - For the positive control, anti-RNA Polymerase, add 1.0µg of antibody per tube.
   - For the negative control, Normal Mouse IgG, add 1.0µg of antibody per tube.
   - For user-provided antibody and controls, add between 1-10µg of antibody per tube. The appropriate amount of antibody needs to be empirically determined.

10. Incubate overnight at 4°C with rotation.
    - It may be possible to reduce the incubation time of the IP. This depends on many factors (antibody, gene target, cell type, etc.) and will have to be tested empirically.

11. Add 60µl of Protein G Agarose for 1 hour at 4°C with rotation.
    - This serves to collect the antibody/antigen/DNA complex.

12. Pellet Protein G Agarose by brief centrifugation (3000-5000 x g for 1 minute) and remove the supernatant fraction.

13. Wash the Protein G Agarose-antibody/chromatin complex by resuspending the beads in 1ml each of the cold buffers in the order listed below and incubating for 3-5 minutes on a rotating platform followed by brief centrifugation (3000-5000 x g for 1 minute) and careful removal of the supernatant fraction:
    a. Low Salt Immune Complex Wash Buffer (Catalog # 20-154), **one wash**
    b. High Salt Immune Complex Wash Buffer (Catalog # 20-155), **one wash**
    c. LiCl Immune Complex Wash Buffer (Catalog # 20-156), **one wash**
    d. TE Buffer (Catalog # 20-157), **two washes**
D. Elution of Protein/DNA Complexes

Prior to starting this section:

- Bring 1M NaHCO₃ to room temperature. A precipitate may be observed but will go into solution once room temperature is achieved. The 1M NaHCO₃ can be vortexed.
- Set water bath to 65°C for use in Section E.

1. Make Elution Buffer for all IP tubes as well as all Input tubes (see Section C, step 7).
   - For each tube, prepare 200µl of elution buffer as follows: 10µl 20% SDS, 20µl 1M NaHCO₃ and 170µl dH₂O.
2. Alternatively, make a large volume to accommodate all tubes. For example, if there are 10 tubes mix together 105µl 20% SDS, 210µl 1M NaHCO₃ and 1.785ml dH₂O.
3. For Input tubes (see Section C, step 7), add 200µl of Elution Buffer and set aside at room temperature until Section E.
4. Add 100µl of Elution Buffer to each tube containing the antibody/agarose complex. Mix by flicking tube gently.
5. Incubate at room temperature for 15 minutes.
6. Pellet agarose by brief centrifugation (3000-5000 x g for 1 minute) and collect supernatant into new microfuge tubes.
7. Repeat steps 4-6 and combine eluates (total volume = 200µl).

E. Reverse Crosslinks of Protein/DNA Complexes to Free DNA

1. To all tubes (IPs and Inputs) add 8µl 5M NaCl and incubate at 65°C for 4-5 hours or overnight to reverse the DNA – Protein crosslinks. After this step the sample can be stored at -20°C and the protocol continued the next day.
2. To all tubes, add 1µl of RNase A and incubate for 30 minutes at 37°C.
3. Add 4µl 0.5M EDTA, 8µl 1M Tris-HCl and 1µl Proteinase K and incubate at 45°C for 1-2 hours.

F. DNA Purification Using Spin Columns

1. Remove one Spin Filter in Collection Tube and one separate Collection Tube for each sample tube from Section E.
2. Add 1ml of Bind Reagent “A” to each 200µl DNA sample tube (IPs and Inputs) and mix well.
   - 5 volumes of Bind Reagent “A” should be used for every 1 volume of sample.
   - A precipitate may be observed. This will not interfere with this procedure.
3. Transfer 600µl of sample/Bind Reagent “A” mixture to the Spin Filter in Collection Tube.
4. Centrifuge for 30 seconds at a minimum of 10,000 x g.
5. Remove the Spin Filter from the Collection Tube, save the Collection Tube and discard the liquid.
   - If a precipitate formed in Step 2, it may be observed in the bottom of the Collection Tube and this will not interfere with this procedure.
6. Put the Spin Filter back into the same Collection Tube.
7. Transfer the remaining 600µl of sample/Bind Reagent “A” mixture from Step 2 into the Spin Filter and repeat steps 4-6.
8. Add 500µl of the Wash Reagent “B” to the Spin Filter in Collection Tube.
9. Centrifuge for 30 seconds at a minimum of 10,000 x g.

10. Remove the Spin Filter from the Collection Tube, save the Collection Tube and discard the liquid.

11. Put the Spin Filter back into the same Collection Tube.

12. Centrifuge for 30 seconds at a minimum of 10,000 x g.

14. Put the Spin Filter into a clean Collection Tube.

15. Add 50μl of Elution Buffer “C” directly onto the center of the white Spin Filter membrane.

16. Centrifuge for 30 seconds at a minimum of 10,000 x g.

17. Remove and discard Spin Filter. Eluate is now purified DNA. It can be analyzed immediately or stored frozen at -20°C.

G. PCR of Controls

Note: Filter-tip pipette tips are recommended for use in this section to minimize risk of contamination.

1. Label the appropriate number of 0.2ml PCR tubes for the number of samples to be analyzed and place on ice.

   - At a minimum, there will be 4 DNA samples to undergo PCR using the Control Primers included in this kit: positive and negative control antibody immunoprecipitations, Input and a no DNA tube as a control for DNA contamination.
   - The Control Primers are specific for the human GAPDH gene. It is recommended that the user design appropriate specific primers (using the guidelines on page 4) for DNA from other species and determine the PCR reaction conditions empirically.

2. Add 2μl of the appropriate sample to the PCR tube and return to ice.

3. Add the appropriate amount of reagents to each PCR reaction tube on ice, adding the H2O first and the Taq polymerase last, as indicated in Table I.

   - It is recommended that the user employ a Hot-Start Taq polymerase. If user is not employing a Hot-Start Taq polymerase, Taq must be added to each tube after the initial denaturation step.
   - If a master reaction mix is desired, dispense enough reagent for one extra tube to account for loss of volume.

4. Place the PCR reaction tubes in a thermal cycler.

6. Remove the PCR tubes. Reactions can be stored at -20°C.

7. Remove 10µl of each PCR reaction for analysis by 4% agarose gel electrophoresis with a 100bp DNA marker. The expected size of the PCR product is 166 base pairs. See Figure B (below) for an example.

The polymerase chain reaction (PCR) is covered by one or more of the following U.S. patents: 4,683,202; 4,683,195; and 4,889,818 issue to Cetus Corporation and owned and licensed by Hoffman-LaRoche Molecular Systems, Inc. Purchase of the EZ ChIP™ Kit does not convey a license to use the PCR process covered by these patents. Purchasers of this product must obtain a license to use the PCR process before performing PCR.

---

**Figure A: DNA Sonication**

Unsheared and sheared chromatin from formalddehyde-crosslinked HeLa cells was prepared by following Section A (all steps) Section B (steps 1-4) and Appendix A (steps 7-9) of the EZ ChIP protocol. 20µl of unsheared (lane 1) and sheared (lane 2) chromatin was then electrophoresed through a 2% agarose gel and stained with ethidium bromide. Lane 2 shows that the majority of the DNA has been sheared to a length between 200bp and 1000bp.

---

**Figure B: PCR Analysis of Chromatin Immunoprecipitation**

Chromatin immunoprecipitation was performed using chromatin from HeLa cells and either anti-RNA Polymerase II (Catalog # 05-623) or Normal Mouse IgG (Catalog # 12-371) as the immunoprecipitating antibody. Purified DNA was then analyzed by PCR using Control Primers specific for the GAPDH promoter. PCR product was observed in the anti-RNA Polymerase II ChIP (lane 3) and not in the Normal Mouse IgG ChIP (lane 2). GAPDH promoter specific DNA was also observed in the Input (lane 4) and not in the “No DNA” PCR control (lane 1).
V. APPENDIX A: Optimization of DNA Sonication

Optimal conditions required for shearing crosslinked DNA to 200-1000 base pairs in length depend on the cell type, cell concentration per lysis buffer and the sonicator equipment, including the power settings and number of pulses. Following the protocol below, determine the optimal conditions required.

1. Generate a cell lysate by following Section A, Steps 1-14, but vary the SDS lysis buffer volume per cell amount to generate at least 4 different microfuge tubes containing a variety of cell equivalent concentrations in the range of $5 \times 10^6$ per ml to $5 \times 10^7$ per ml. Each microfuge tube should contain approximately 300-400µl of cell lysate.

2. Be sure to keep the samples on wet ice at all times.
   - The sonication generates heat which will denature the chromatin.

3. Remove $1 \times 10^5$ cell equivalents from each condition prior to sonication for analysis of unsheared DNA.

4. For each cell concentration, sonicate each tube for a different number of 10 sec pulses depending on the number of tubes. For example, sonicate the first tube for 1 x 10 seconds, the second tube for 2 x 10 seconds, the third tube for 3 x 10 seconds and the fourth tube for 4 x 10 seconds.

5. Repeat for all cell concentrations.

6. Remove 5µl of the sonicated chromatin from each condition to a fresh tube.

7. To all the 5µl samples (unsheared and sheared), add 90µl ddH2O and 4µl 5M NaCl.

8. Incubate at least 4-5 hours to overnight at 65°C to reverse the DNA – protein crosslinks.

9. Add 1µl of RNase A and incubate for 30 minutes at 37°C.

10. Add 2µl 0.5M EDTA, 4µl 1M Tris-HCl and 1µl Proteinase K and incubate at 45°C for 1-2 hours.

11. Load 10µl (1 x $10^4$ cell equivalents) and 20µl (2 x $10^4$ cell equivalents) on a 1-2% agarose gel with a 100bp DNA marker.
   - Loading different amounts helps to avoid under- or over-loading.

12. Observe which of the shearing conditions gives a smear of DNA in the range of 200bp-1000bp. See Figure A (page 12) for an example.

13. Repeat optimization of the shearing conditions if the results indicate that the resulting DNA is not in the desired size range. Once optimal conditions have been determined, it is advised that the user does not alter the cell concentration or volume of lysate per microfuge tube for subsequent chromatin immunoprecipitation experiments.
VI. APPENDIX B: Preparation of Fresh 18.5% Formaldehyde

This recipe is for making fresh 18.5% formaldehyde from powdered paraformaldehyde to use immediately in the EZ ChIP™ protocol. Use appropriate safety precautions when performing this procedure.

1. Add 4.8ml of distilled water to a 50ml conical plastic tube.
2. Add 0.925g paraformaldehyde.
3. Add 35µl of 1N KOH.
4. Cap tube tightly and place in a 400-600ml glass beaker filled with approximately 200ml of water.
5. Microwave beaker with tube until water in beaker begins boiling.
6. Remove beaker and vortex tube until paraformaldehyde begins dissolving.
7. Repeat steps 5 & 6 until paraformaldehyde is completely in solution. This step may need to be repeated several times.
8. Store on ice until cool.
9. Use immediately.

| Crosslinking                      | Not enough or too much crosslinking         | The appropriate amount of formaldehyde and time of crosslinking may need to be determined empirically. Conduct a time course at a fixed formaldehyde concentration and/or investigate a range of formaldehyde concentrations for a fixed time.  
HINT: Histones may not need to be crosslinked since they are tightly associated with DNA. |
| Cell Lysis                        | Inefficient disruption of cells             | It is important to have enough lysis buffer per cell concentration. Follow the guidelines in this protocol. Also, check the cell lysis by looking at a 10ul portion of the cell lysate under the microscope for intact cells. |
| Chromatin Shearing                | Not enough/too much sonication              | Follow Appendix A to obtain the appropriate sized DNA.                                     |
|                                  | Denaturation of proteins from overheating sample | Keep the sample on ice during the sonication. Shorten the time the sample and increase the number of times the sample is sonicated. |
| Antibody doesn’t recognize protein in fixed chromatin | Choose an antibody directed to a different epitope of the antigen. Decrease the amount or time of formaldehyde fixation. |
| Addition of Primary Antibody      | Not enough or too much chromatin            | Perform IP from a dilution series of antibody with a fixed amount of chromatin or vice versa. |
|                                  | Insufficient incubation time                | • Incubate the antibody of interest with the chromatin at 4°C overnight.  
• Select a different antibody with higher affinity.  
• Perform a Western blot of the IP’d protein to make sure the antibody can IP the antigen of interest. |
| Addition of Secondary Reagent – Protein G agarose | Not enough beads | The Protein G Agarose is a 50% slurry of beads suspended in buffer. The agarose beads settle to the bottom of the tube over time. Make sure the Protein G Agarose is well mixed prior to removing the appropriate volume for IP.  
Incorrect Antibody Class or Isotype | Check that the subclass and isotype of the antibody can bind Protein G. Protein G is not recommended for IgM or chicken Ig. |
